### What this course is about.

The first part of this course is Statistical Mechanics. Starting from Schrödinger's equations for electrons and atoms, we learn how to calculate the macroscopic properties in thermodynamics, such as entropy and heat capacity.

The second part is about experimental methods at low temperatures. We learn how statistical mechanics can be used to understand the behaviour of matter at very low temperatures, and to develop the cooling techniques needed to reach these temperatures.

Part 1: Statistical Mechanics

- 1. Basic statistics.
- 2. Distinguishable particles.
- 3. Paramagnetic salts and oscillators.
- 4. Indistinguishable particles and the ideal gas.
- 5. Electrons in metals.
- 6. Photons, phonons and Bose-Einstein condensation.

Part 2: Low Temperature Cooling Techniques

- 7. Cooling techniques and liquid Helium.
- 8. The dilution refrigerator.
- 9. The magnetic refrigerator.

Contents

- 1.1 Tossing a coin
- 1.2 Probability, mean and standard deviation
- 1.3 Coin tossing and temperature

Part 1: Statistical Mechanics

Why coin tossing?

We often use the familiar coin tossing to develop the techniques. There is a rather broad analogy with the quantum mechanics:

- 1. Head or tail – 2 energy levels
- 2. Many coins – many atoms
- 3. number of heads - energy, or temperature

Deining some terms

Define the notations:

H = head  
T = tail

Suppose we toss a coin 4 times. The possible outcomes are:

4 heads (4H), or HHHH

3 heads 1 tail (3H1T). This could be in different orders:  
HHHT, HHTH, HTTH or THHH.

2 heads 1 tail (2H2T)

and so on.

Aim

To understand the basic statistical methods required.

Objectives

- 1. To write down the outcomes of tossing a coin.
- 2. To explain the microstate and the macrostate.
- 3. To predict the most probable macrostate in coin tossing.
- 4. To explain the terms expectation, variance and standard deviation.
- 5. To use the binomial distribution in coin tossing.
- 6. To describe the most probable macrostate for large number of tosses.

Contents

1.1 Tossing a coin

Some calculations	
Let	
$N$ = no. of times to flip the coin	
$\Omega$ = no. of times to get $n$ heads	
Using combinations ( ${}^N C_n$ ), we find	
$\Omega = \frac{N!}{n!(N-n)!} \quad (1)$	
We can use this to find the number of microstates. We flip the coin 4 times, so $N = 4$ . For the macrostate $2H2T$ , $n = 2$ .	
The above formula gives the number of microstate as $\Omega = 4!/(2!2!) = 6$ , which is what we got on the previous page.

Contents	

1.2 Probability, mean and standard deviation

Level of description	
There are a few ways to describe the outcome.	
If we say 3H1T, we know there is only 1 tail, but we don't know the order of tail.	
If we say HTHH, then we know it is the second toss that is tail.	
We shall use the following 2 ways:	
1. Macrostate.	
Some, but not all details are specified, such as 3H1T. It is the set of all outcomes that have the specified features.	
2. Microstate.	
This is a full description, such as HTHH. This tells us the exact outcome.	
PHYS393/Hock	16
2009-2010	
The most probable macrostate.	

When we toss a coin 4 times, we can define a macrostate by the number of H. Then there are 5 macrostates:

$x$	Macrostate	Microstates
0	4T	TTTT
1	1H3T	TTTH, TTHT, THTT, HTTT
2	2H2T	HHTT, HTHT, THHT, THTH, TTHH, HTTH
3	3H1T	HHHT, HHTH, HTHH, THHH
4	4H	HHHH

The most probable macrostate is the one with the most microstates. That would be 2H2T, or  $x = 2$ .

Mean and standard deviation	Very large number of tosses
<p>Suppose we toss the coin <math>n</math> times and record the number of H. Suppose we repeat this many times.</p> <p>We would get a sample of data for <math>x</math>, e.g. <math>\{2, 0, 1, 3, 2, 2, 3, 0, \dots\}</math></p> <p>In statistics, we are often interested in two numbers - the mean and the standard deviation.</p> <p>The mean is the simple average.</p> <p>The standard deviation tells us how much the numbers in the data deviate from the mean.</p>	<p>We are interested in the properties macroscopic objects with very large number of atoms.</p> <p>The total energy of the atoms would determine the temperature of an object.</p> <p>At room condition, the object temperature stays constant, even though individual atoms would change energies through vibration.</p> <p>Imagine tossing a coin a large number of times. Would the total number of heads stay relative constant?</p> <p>We can find out using the binomial distribution.</p>

Basic ideas in probability and statistics	
<p>If we know the probability distribution <math>P(x)</math>, we can also calculate the mean and standard deviation without actually tossing the coin.</p> <p>The mean is given by</p> $\mu = \sum x P(x).$ <p>The standard deviation is the root mean square of <math>x - \mu</math>. So it is essentially a kind of average of how much <math>x</math> deviates from <math>\mu</math>.</p> <p>It is given by</p> $\sigma = \sqrt{\sum (x - \mu)^2 P(x)}.$ <p>More explanation can be found in:</p> <p><a href="http://en.wikipedia.org/wiki/Expected_value">http://en.wikipedia.org/wiki/Expected_value</a>  <a href="http://en.wikipedia.org/wiki/Standard_deviation">http://en.wikipedia.org/wiki/Standard_deviation</a></p>	<p>Suppose a coin is tossed 2 times. The possible outcomes are:</p> <p>TT HT TH HH</p> <p>Let <math>x</math> be the number of heads. Let <math>n</math> be the total number of outcomes.</p> <p>Let <math>P(x)</math> be probability of getting <math>x</math> heads. This is given by <math>P(x) = x/n</math>.</p> <p><math>P(0) = 1/4</math>  <math>P(1) = 2/4</math>  <math>P(2) = 1/4</math></p>

A hot cup of tea contains an extremely large number of molecules of water rapidly exchanging energy with one another, and with the surrounding cup and air. At any one time, the energy of a particular molecule could quite random.

Yet, over the period of a few minutes, the temperature of the tea would remain fairly constant.

The temperature is a measure of the total energy of the molecules.

Suppose we toss a number of coins. Each time we toss, the outcome of a particular coin would be random.

Suppose the coin is the molecule. Suppose further that T is the ground state and H the excited state of 2 energy levels.

The standard deviation is relevant to the idea of macrostates that we want to develop.

We are particularly interested in what it means if the standard deviation becomes very small.

Recall that the standard deviation is a measure of the average deviation of  $x$  from the mean.

So if the standard deviation is small, it means that most of the data is very close to the mean value.

If we look at a histogram of the data, it would look more sharply peaked.

## Contents

The total number of H would then be the total energy, or temperature. We would of course expect this total to be quite different each time we toss.

But what if we have an extremely large number of coins? Is it possible then that the total number would not change very much?

It turns out that we can calculate this deviation quite easily using the binomial distribution.

## 1.3 Coin tossing and temperature

Lets get some idea of how  $\sigma$  changes a  $N$  is increased. For a fair coin  $p = q = 1/2$ .

$N$	$\sigma (= \sqrt{Npq})$
4	1
400	10
40000	100
4000000	1000

It looks like the number of heads changes more from one toss to the next, as the number of coins is increased.

But if we plot the distribution on a graph:

we would find that it gets more sharply peaked!

A reference quantity

The reason is because, on the graph, we are looking at the standard deviation relative to the total number of coins  $N$ .

So, although 10 is large than 1, 10/400 would be smaller than 1/4.

This way of looking at it reminds us that to determine whether the change of a quantity is large, we need to have something meaningful to compare with.

For example, when we say the temperature of a cup of tea does not change much, we are really comparing it with the temperature of the tea itself, which could be at 70 deg Celsius, or 343 K.

Let  $p$  be probability of getting a Head, and  $q$  the probability of getting a Tail.

If we have a fair coin, then  $p = q = 1/2$ .

Suppose we toss a coin  $N$  times.

The probability of getting  $x$  heads is given by the binomial distribution:

$$P(x) = {}^N C_n p^n q^{N-n}.$$

For an explanation of this formula, see:

[http://en.wikipedia.org/wiki/Binomial\\_distribution](http://en.wikipedia.org/wiki/Binomial_distribution)

Mean and standard deviation

When we toss a coin  $N$  times, suppose that we get  $x$  heads.

When we toss  $N$  times again, we are likely to get a different  $x$ .

The mean value of  $x$  is given by a sum over  $x$ , weighted by the probabilities:

$$\mu = \sum_{x=0}^N x P(x) = Np.$$

The standard deviation is given by:

$$\sigma = \sqrt{\sum_{x=0}^N (x - \mu)^2 P(x)} = \sqrt{Npq}.$$

Both formulae can be derived by substituting the binomial distribution  $P(x) = {}^N C_n p^n q^{N-n}$ .

Very broadly, we may draw the following analogy:

1. H is the higher energy state, T is the lower one.
2. One toss of a coin is one atom.
3. The number of H is the temperature.

In a real material at room temperature, each atom could take on energy random, through colliding with other atoms.

Because the number of atoms is huge, when we measure the temperature with a thermometer, we hardly see any fluctuation - even though the energy of each atom is changing all the time.

What we have learnt so far.

1. A coin may represent a particle with two energy levels.
2. The macrostate could be specified by the number of heads, and the microstate by the actual ordering.
3. The most probable macrostate in coin tossing is  $x = N/2$ .
4. The binomial distribution can be used to calculate the mean and standard deviation in coin tossing.
5. For large number of tosses, it is very unlikely to have macrostates different from  $x = N/2$ .

In the case of the coins, we should therefore be comparing the standard deviation with the total number of coins  $N$ .

$x$  is the actual number of heads in one microstate.

The average of deviation of this number from the mean, as a fraction of  $N$ , is  $\sigma/N = \sqrt{pq}/N$ .

When  $N$  is very large, this fraction approaches zero.

The dotted curve is the smallest  $N$ , the solid curve the largest  $N$ . Notice that the peak gets narrower for large  $N$ .

If  $N$  is as big as the number of atoms in a real material, the peak becomes extremely narrow.

Then  $x = N/2$  becomes almost the only macrostate.

### Exercise 1

Suppose a biased coin is tossed 2 times. The probability distribution for 0, 1 and 2 heads are given by 0.36, 0.48 and 0.16, respectively. Find the mean and standard deviation of the number of heads.

### Answer

Let  $x$  be the number of heads. The distribution given is

$x$	$P(x)$
0	0.36
1	0.48
2	0.16

---

### Some exercises

---

The mean is  $\mu = \sum xP(x) = 0 \times 0.36 + 1 \times 0.48 + 2 \times 0.16 = 0.8$ .

(Out of 2 tosses, we only get 0.8 heads on average. Obviously, this coin is biased towards the tail.)

$x$	$x - \mu$	$(x - \mu)^2$
0	-0.8	0.64
1	0.2	0.04
2	1.2	1.44

The standard deviation is

$$\begin{aligned}\sigma &= \sqrt{\sum (x - \mu)^2 P(x)} \\ &= \sqrt{0.64 \times 0.36 + 0.04 \times 0.48 + 1.44 \times 0.16} = 0.48.\end{aligned}$$
